Computer Science & Engineering**

CPSC 410 – Operating Systems I

Virtualizing Memory: Faster with TLB

Keith Perkins

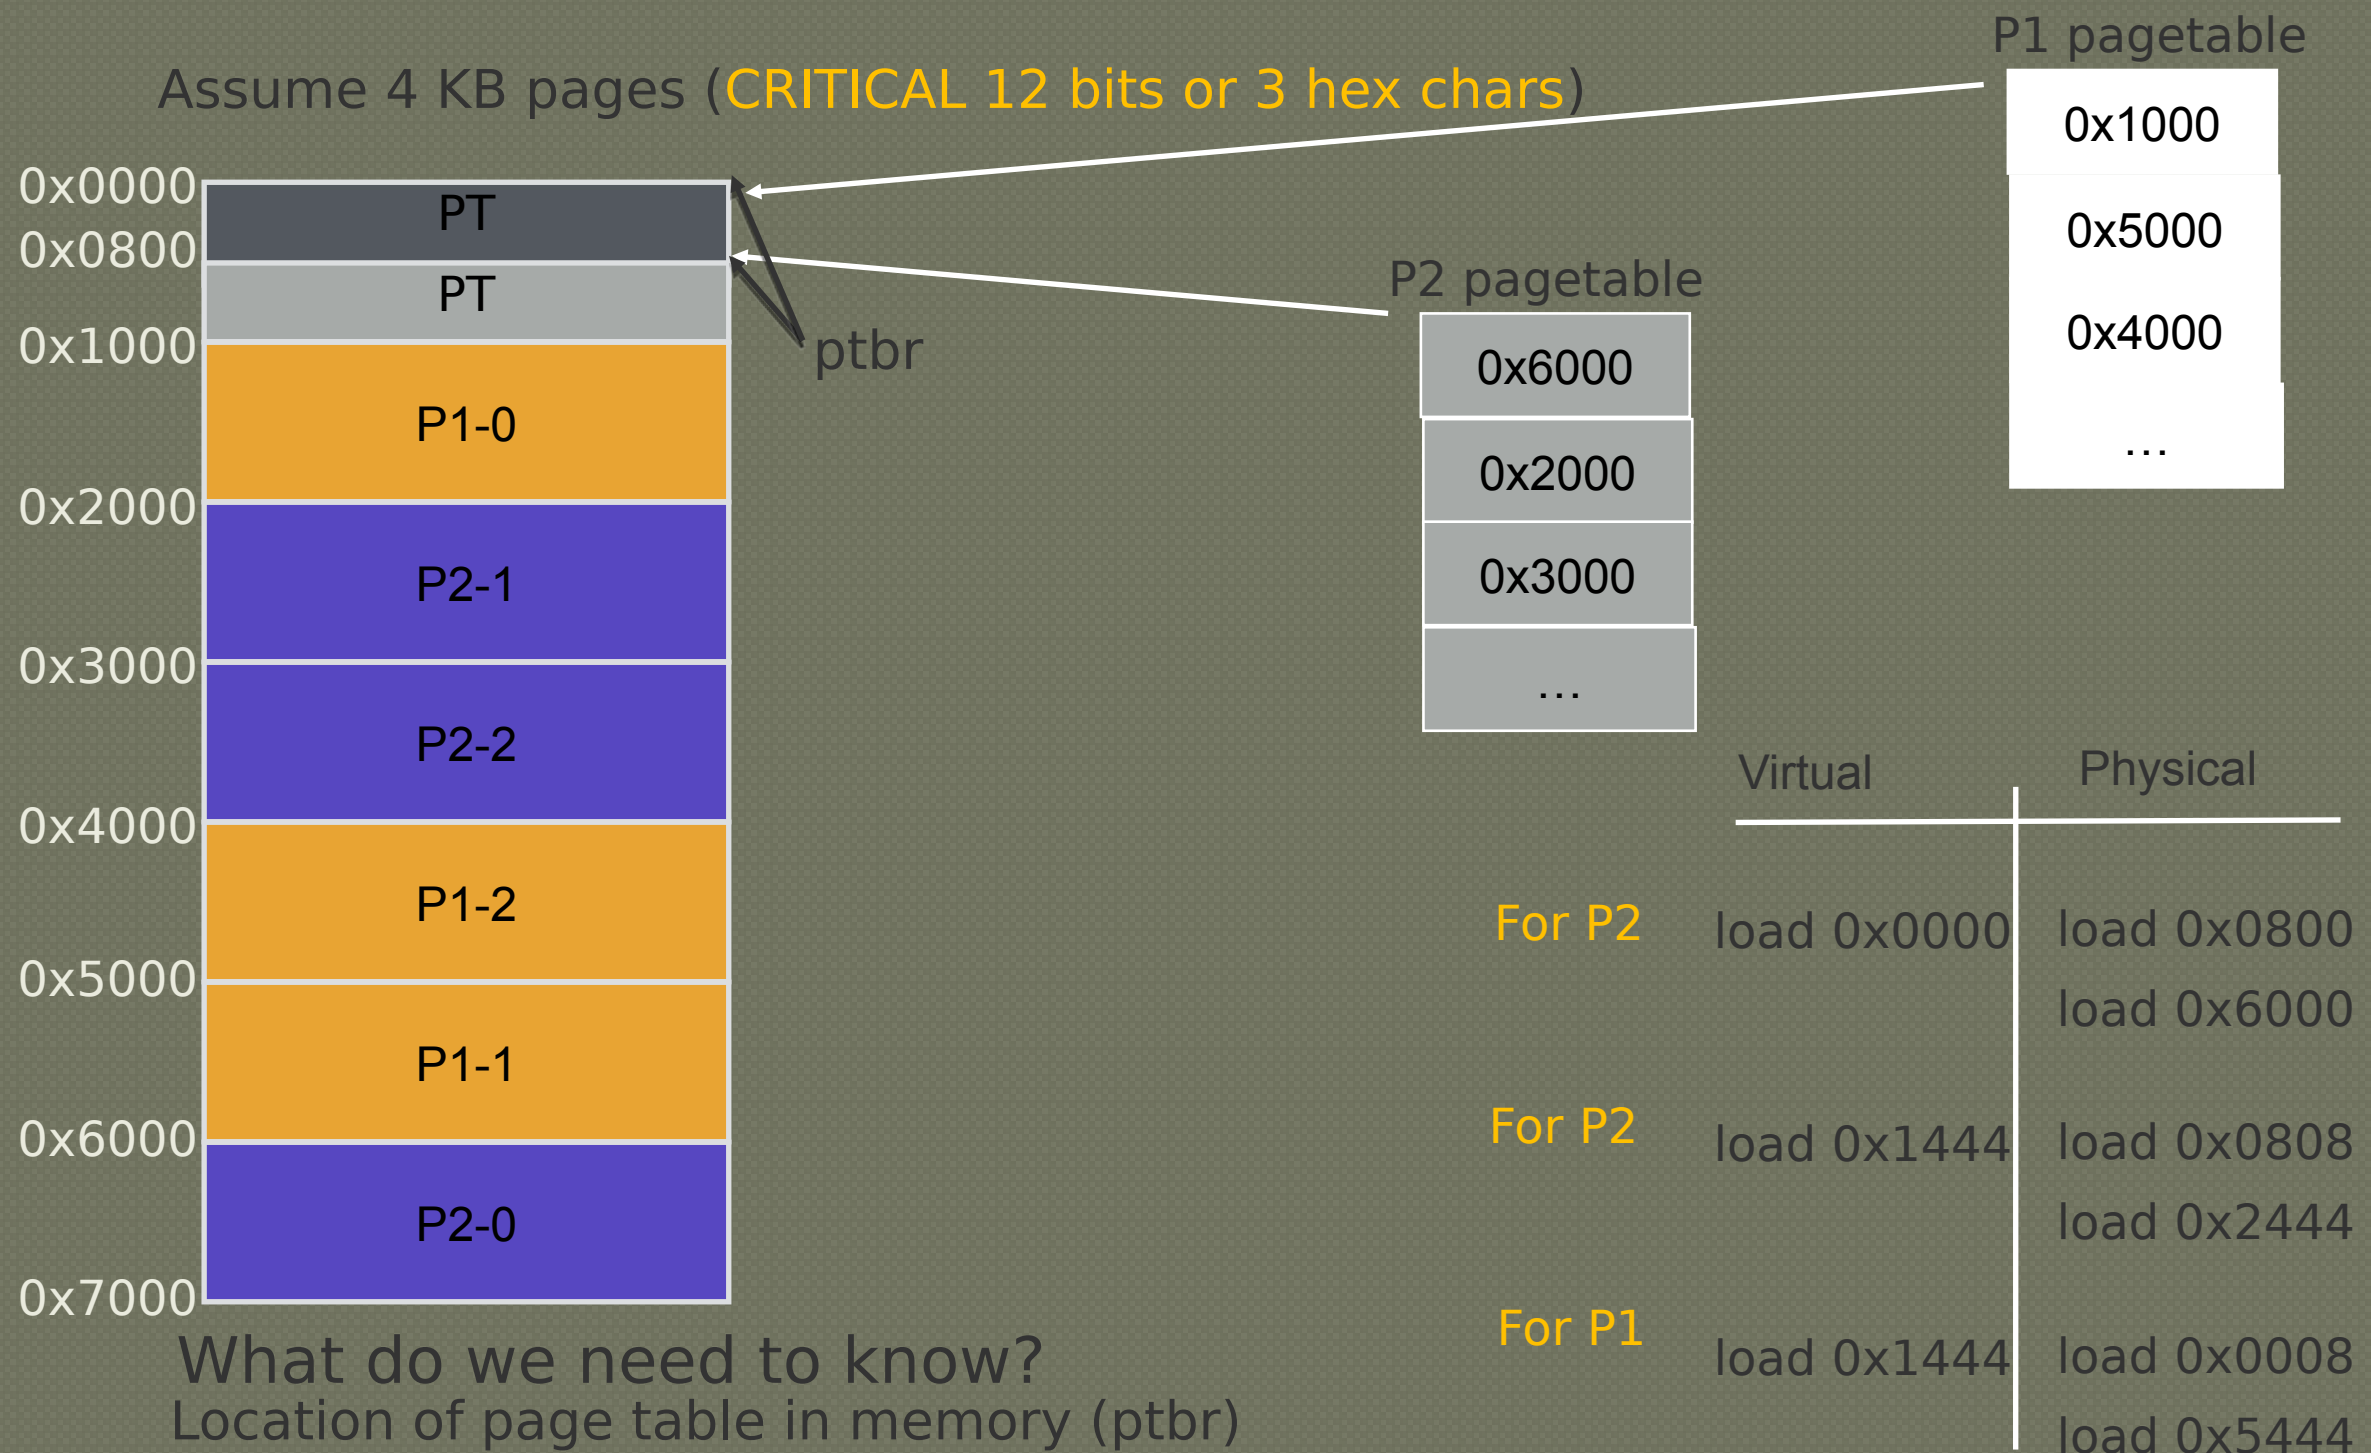

Adapted from “CS 537 Introduction to Operating Systems” Arpaci-Dusseau

Questions answered in this lecture:

-  Review paging...
-  How can page translations be made faster?
-  What is the basic idea of a TLB (Translation Lookaside Buffer)?
-  What types of workloads perform well with TLBs?
-  How do TLBs interact with context-switches?

Review: Paging

Assume 4 KB pages (**CRITICAL 12 bits or 3 hex chars**)

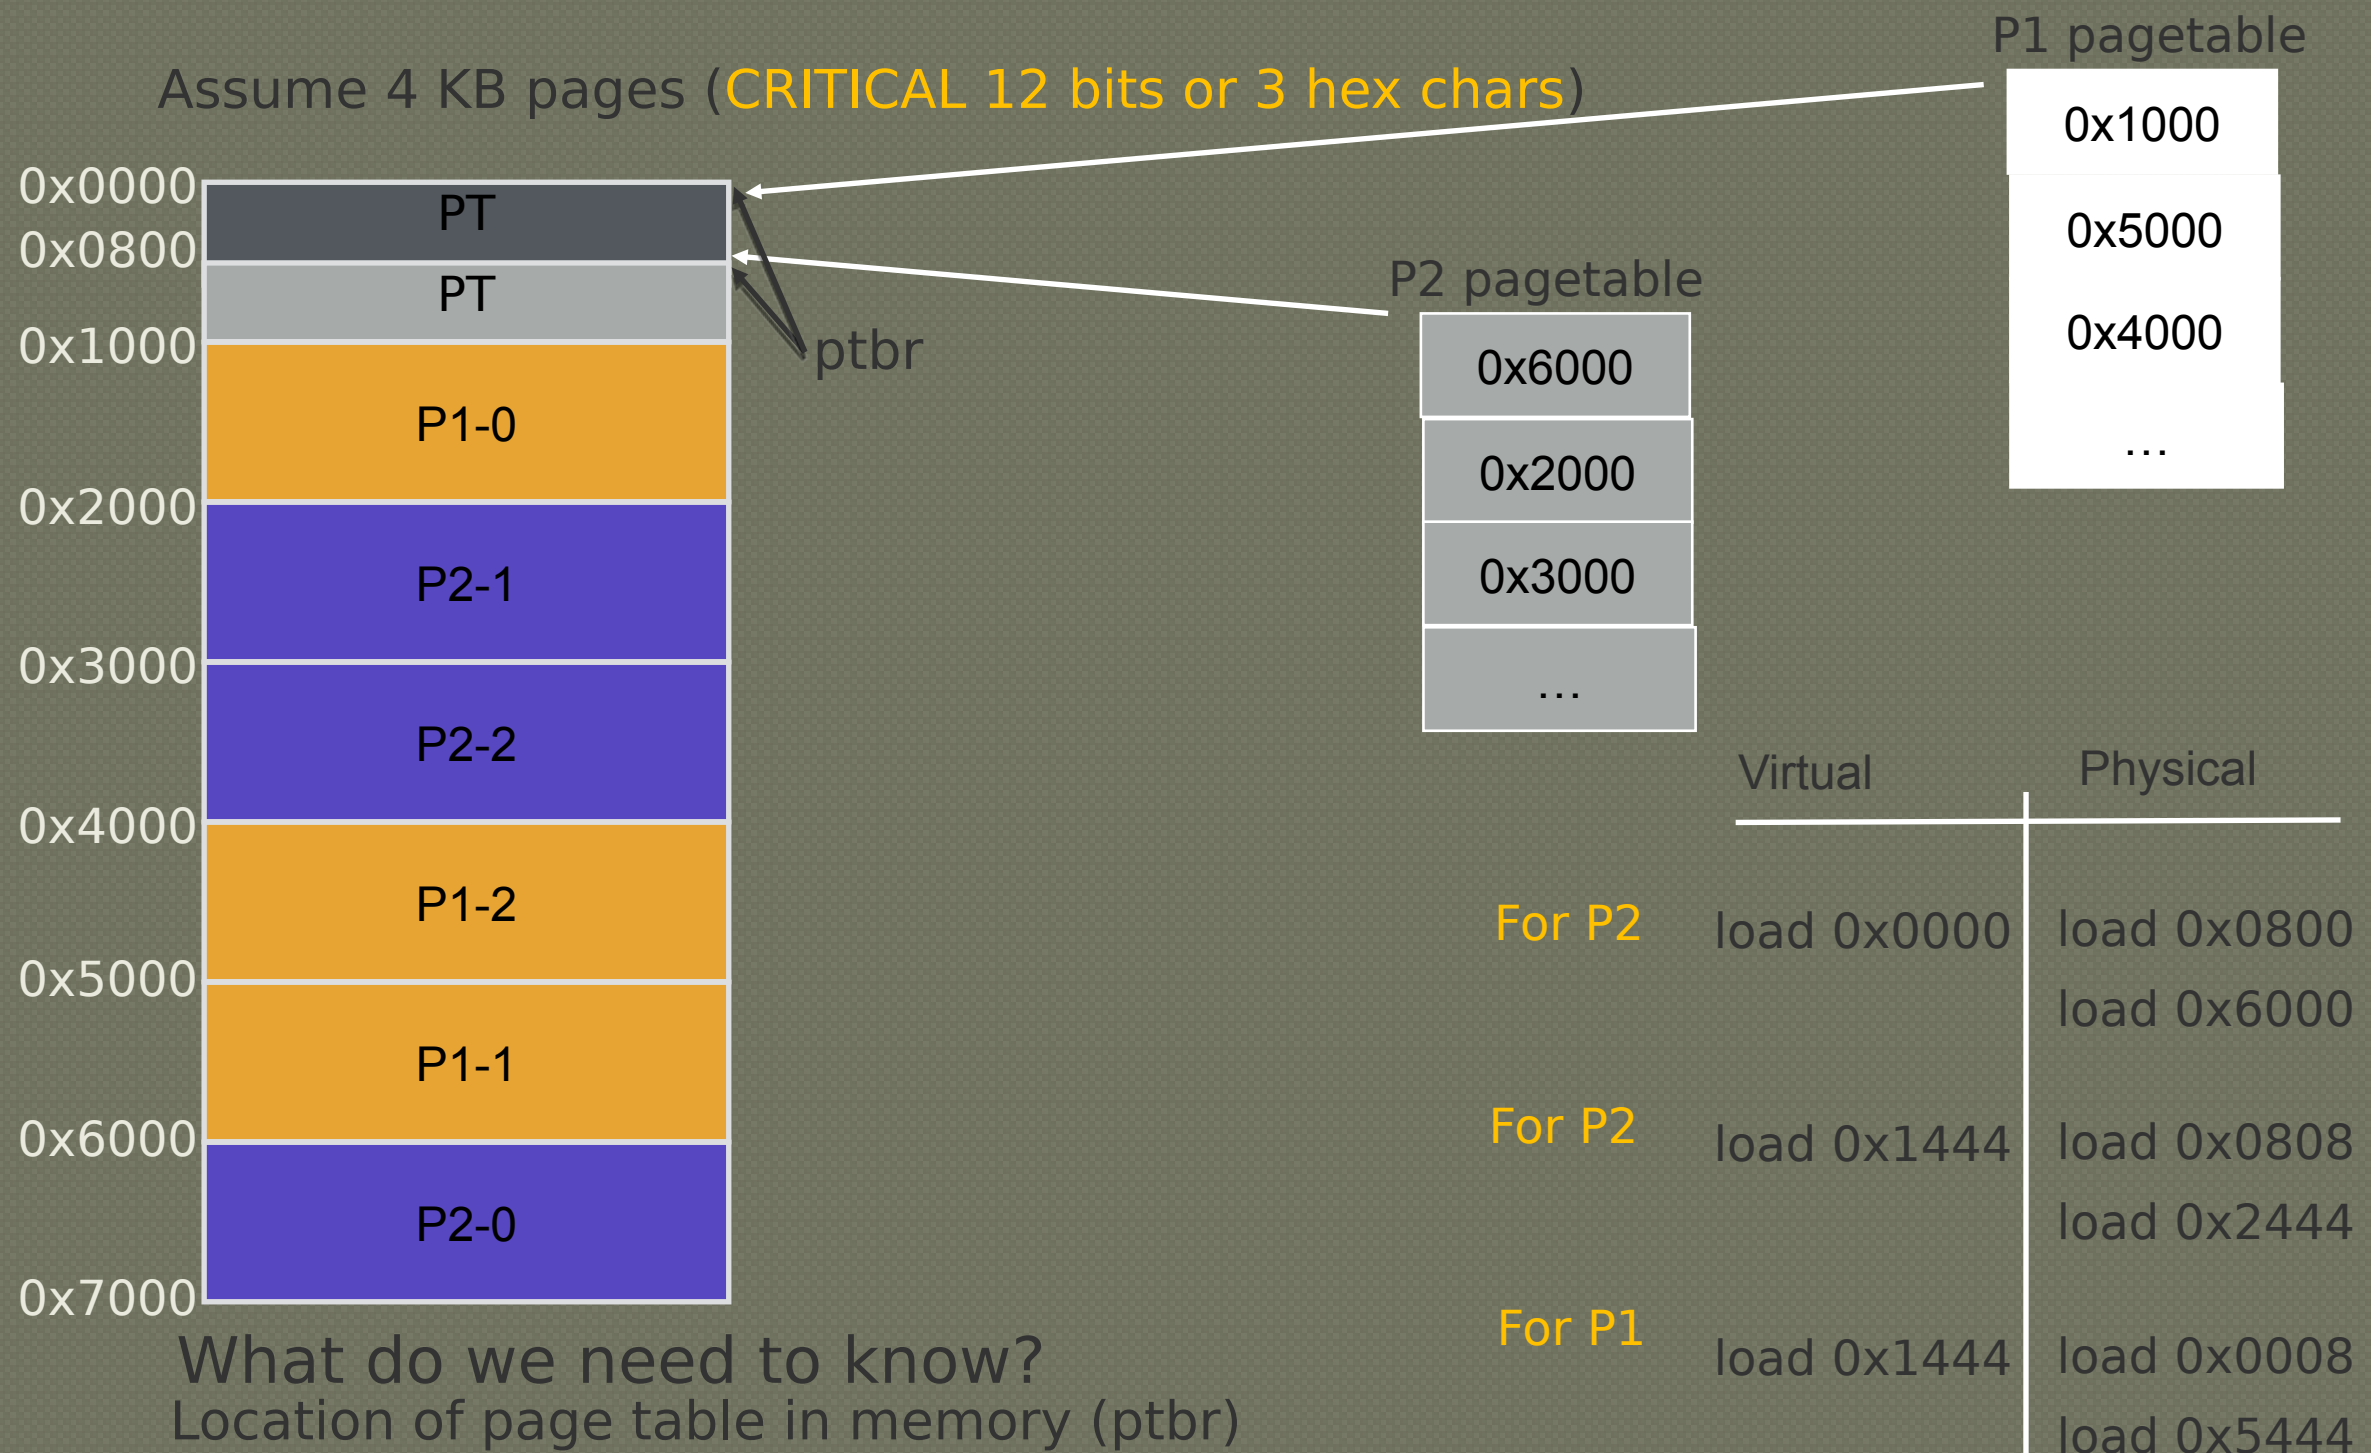

What do we need to know?

Location of page table in memory (ptbr)

Size of each page table entry (**assume 8 bytes**)

Review: Paging

Assume 4 KB pages (**CRITICAL 12 bits or 3 hex chars**)

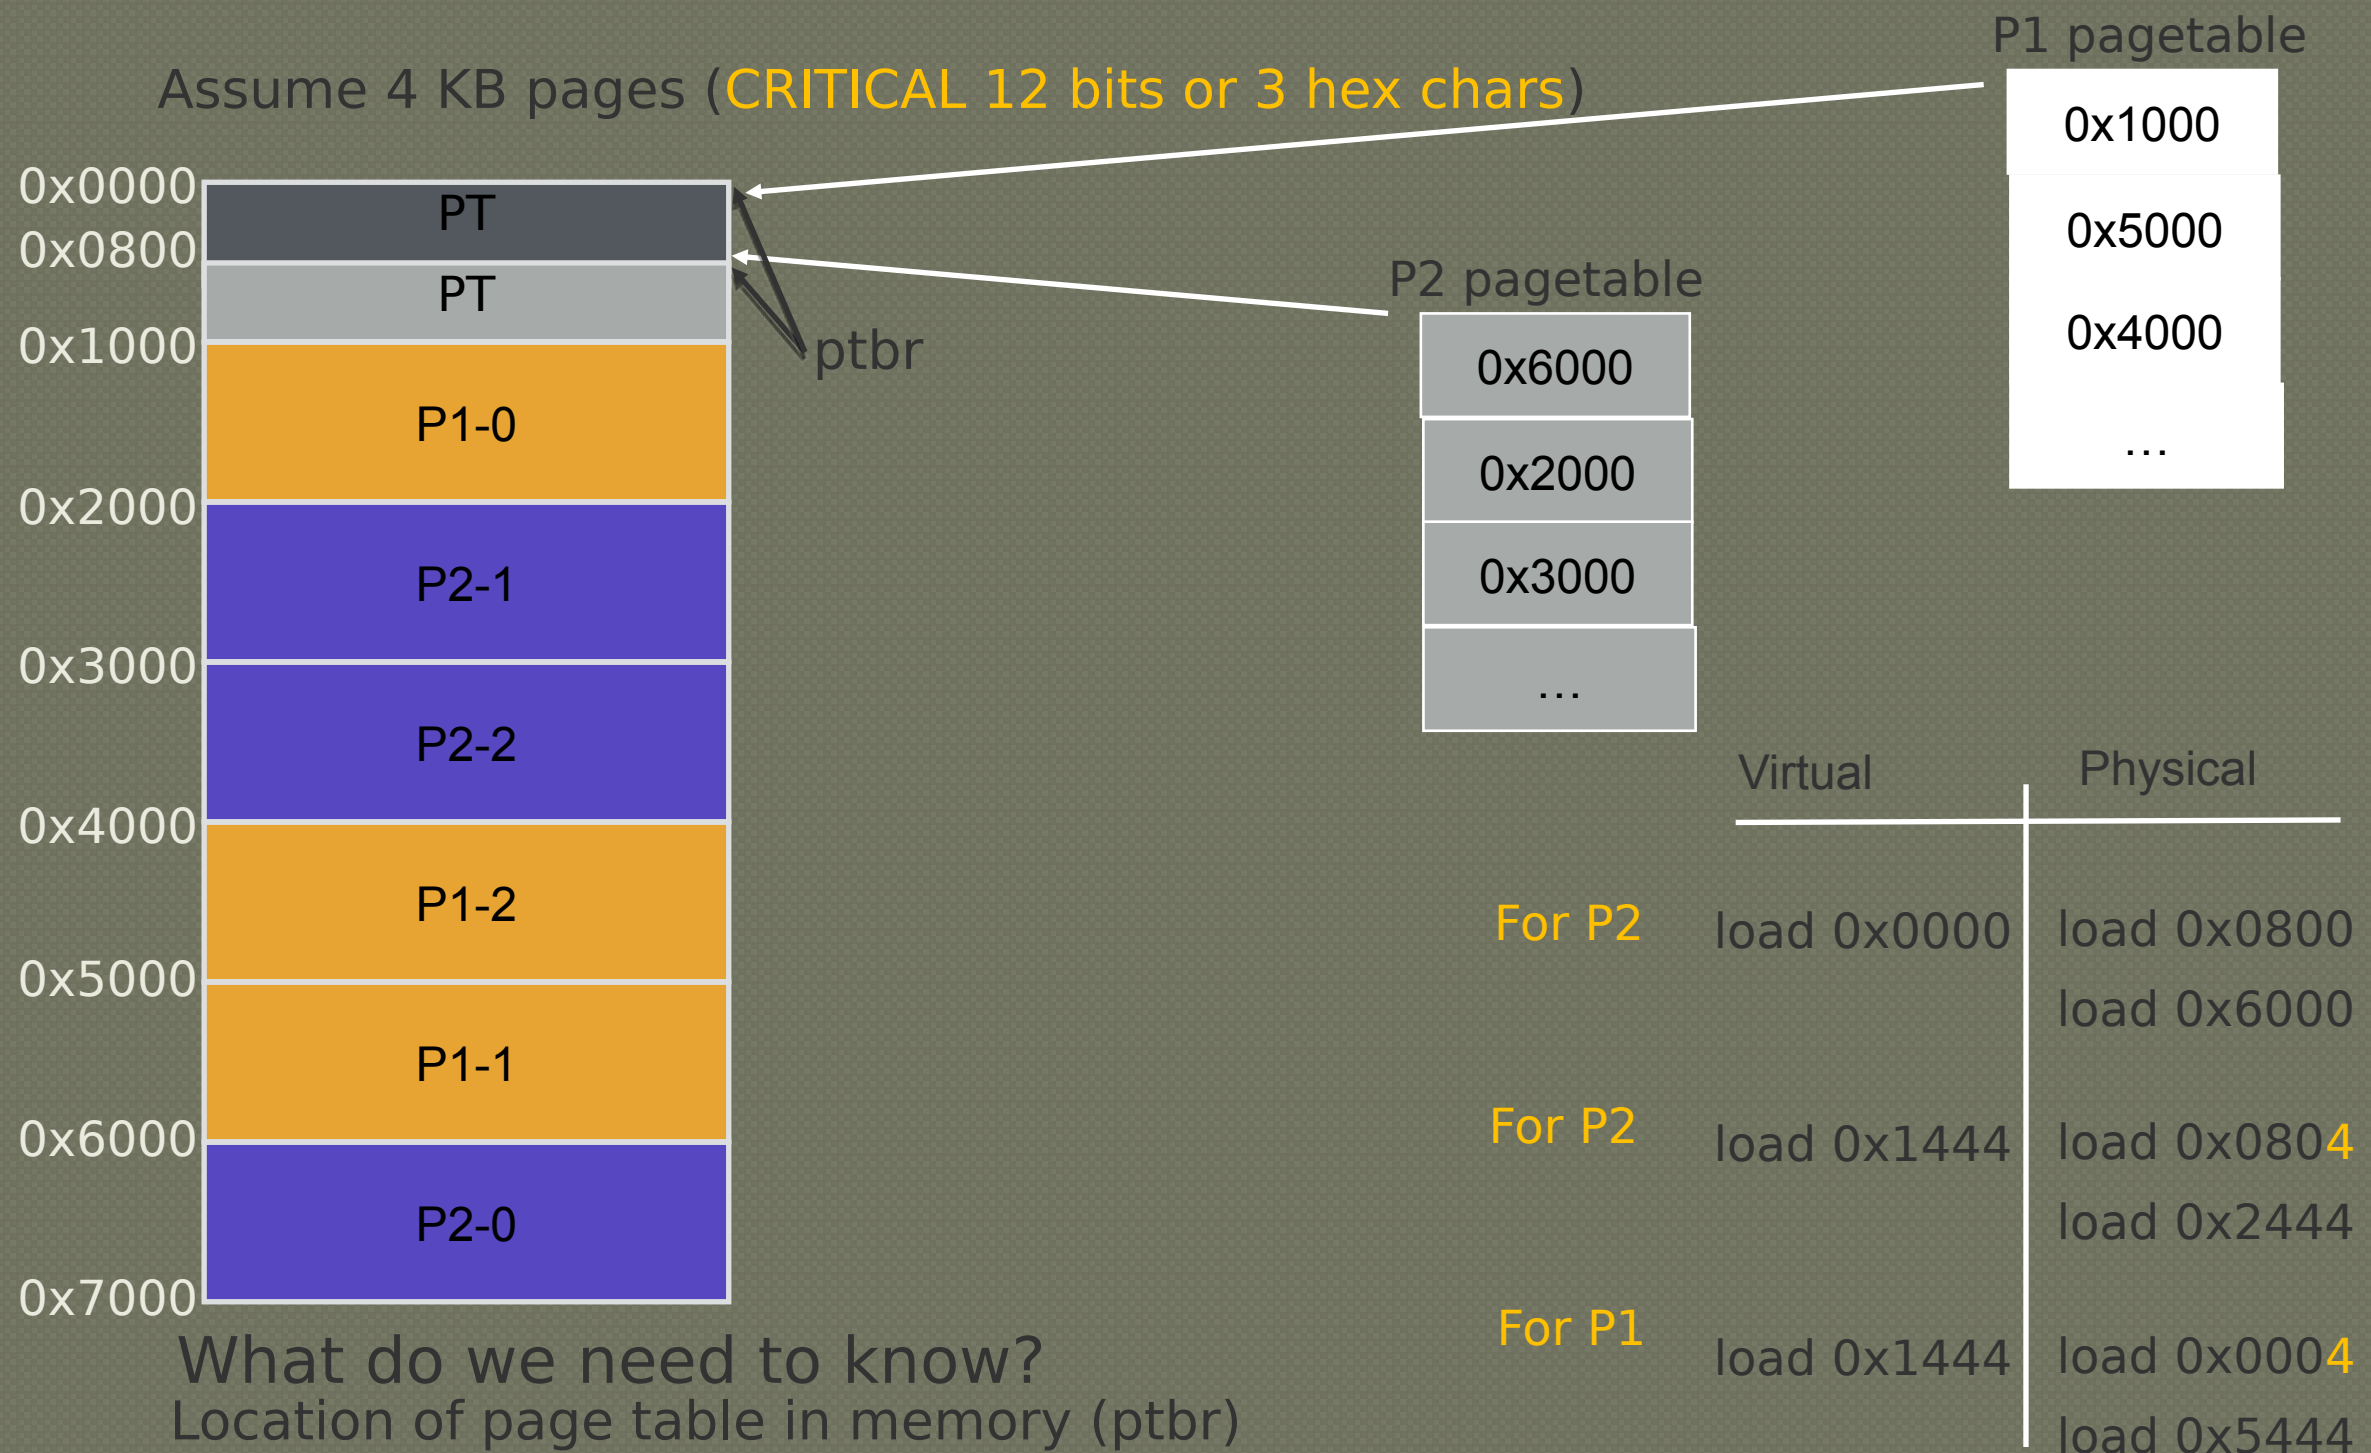

What do we need to know?

Location of page table in memory (ptbr)

Size of each page table entry (**assume 8 bytes – What if 4 bytes?**)

Review: Paging

Assume 4 KB pages (**CRITICAL 12 bits or 3 hex chars**)

What do we need to know?

Location of page table in memory (ptbr)

Size of each page table entry (**assume 8 bytes – What if 4 bytes?**)

Review: Paging PROS and CONS

Advantages

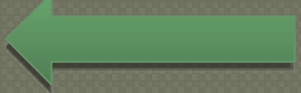

- No external fragmentation
 - don't need to find contiguous RAM
- All free pages are equivalent
 - Easy to manage, allocate, and free pages

Disadvantages

- Page tables are too big
 - **Must have one entry for every page of address space**
- Accessing page tables is too slow [**today's focus**]
 - Doubles number of memory references per instruction

Translation Steps

H/W: for each mem reference:

- (cheap) 1. extract **VPN** (virt page num) from **VA** (virt addr)
- (cheap) 2. calculate addr of **PTE** (page table entry = $PTBR + VPN$)
- (expensive) 3. read **PTE** from memory 
- (cheap) 4. extract **PFN** (page frame num)
- (cheap) 5. build **PA** (phys addr)
- (expensive) 6. read contents of **PA** from memory into register

Which steps are expensive?

Which expensive step will we avoid in today's lecture?

BTW Don't always have to read PTE from memory!

Example: Array Iterator

```
int sum = 0;
for (i=0; i<N; i++) {
    sum += a[i];
}
```

Assume 'a' starts at
0x3000

Ignore instruction fetches

What virtual addresses?

load 0x3000

load 0x3004

load 0x3008

load 0x300C

...

What physical addresses?

load 0x100C

load 0x7000 + 0

load 0x100C

load 0x7000 + 4

load 0x100C

load 0x7000 + 8

load 0x100C

load 0x7000 + 12

0x1000	0	
0x1004	1	
0x1008	2	
0x100c	3	0x7000

Aside: What can you infer?

- ptbr: 0x1000; PTE 4 bytes each
- VPN 3 -- PPN 7
- Have 12 bits of offset

Observation: Repeatedly access same PTE because
program repeatedly accesses same virtual page

Strategy: Cache Page Translations

TLB: Translation Lookaside Buffer

Array Iterator (w/ TLB)

```
int sum = 0;
for (i = 0; i < 2048; i++) {
    sum += a[i];
}
```

Assume following virtual address stream:

load 0x1000

load 0x1004

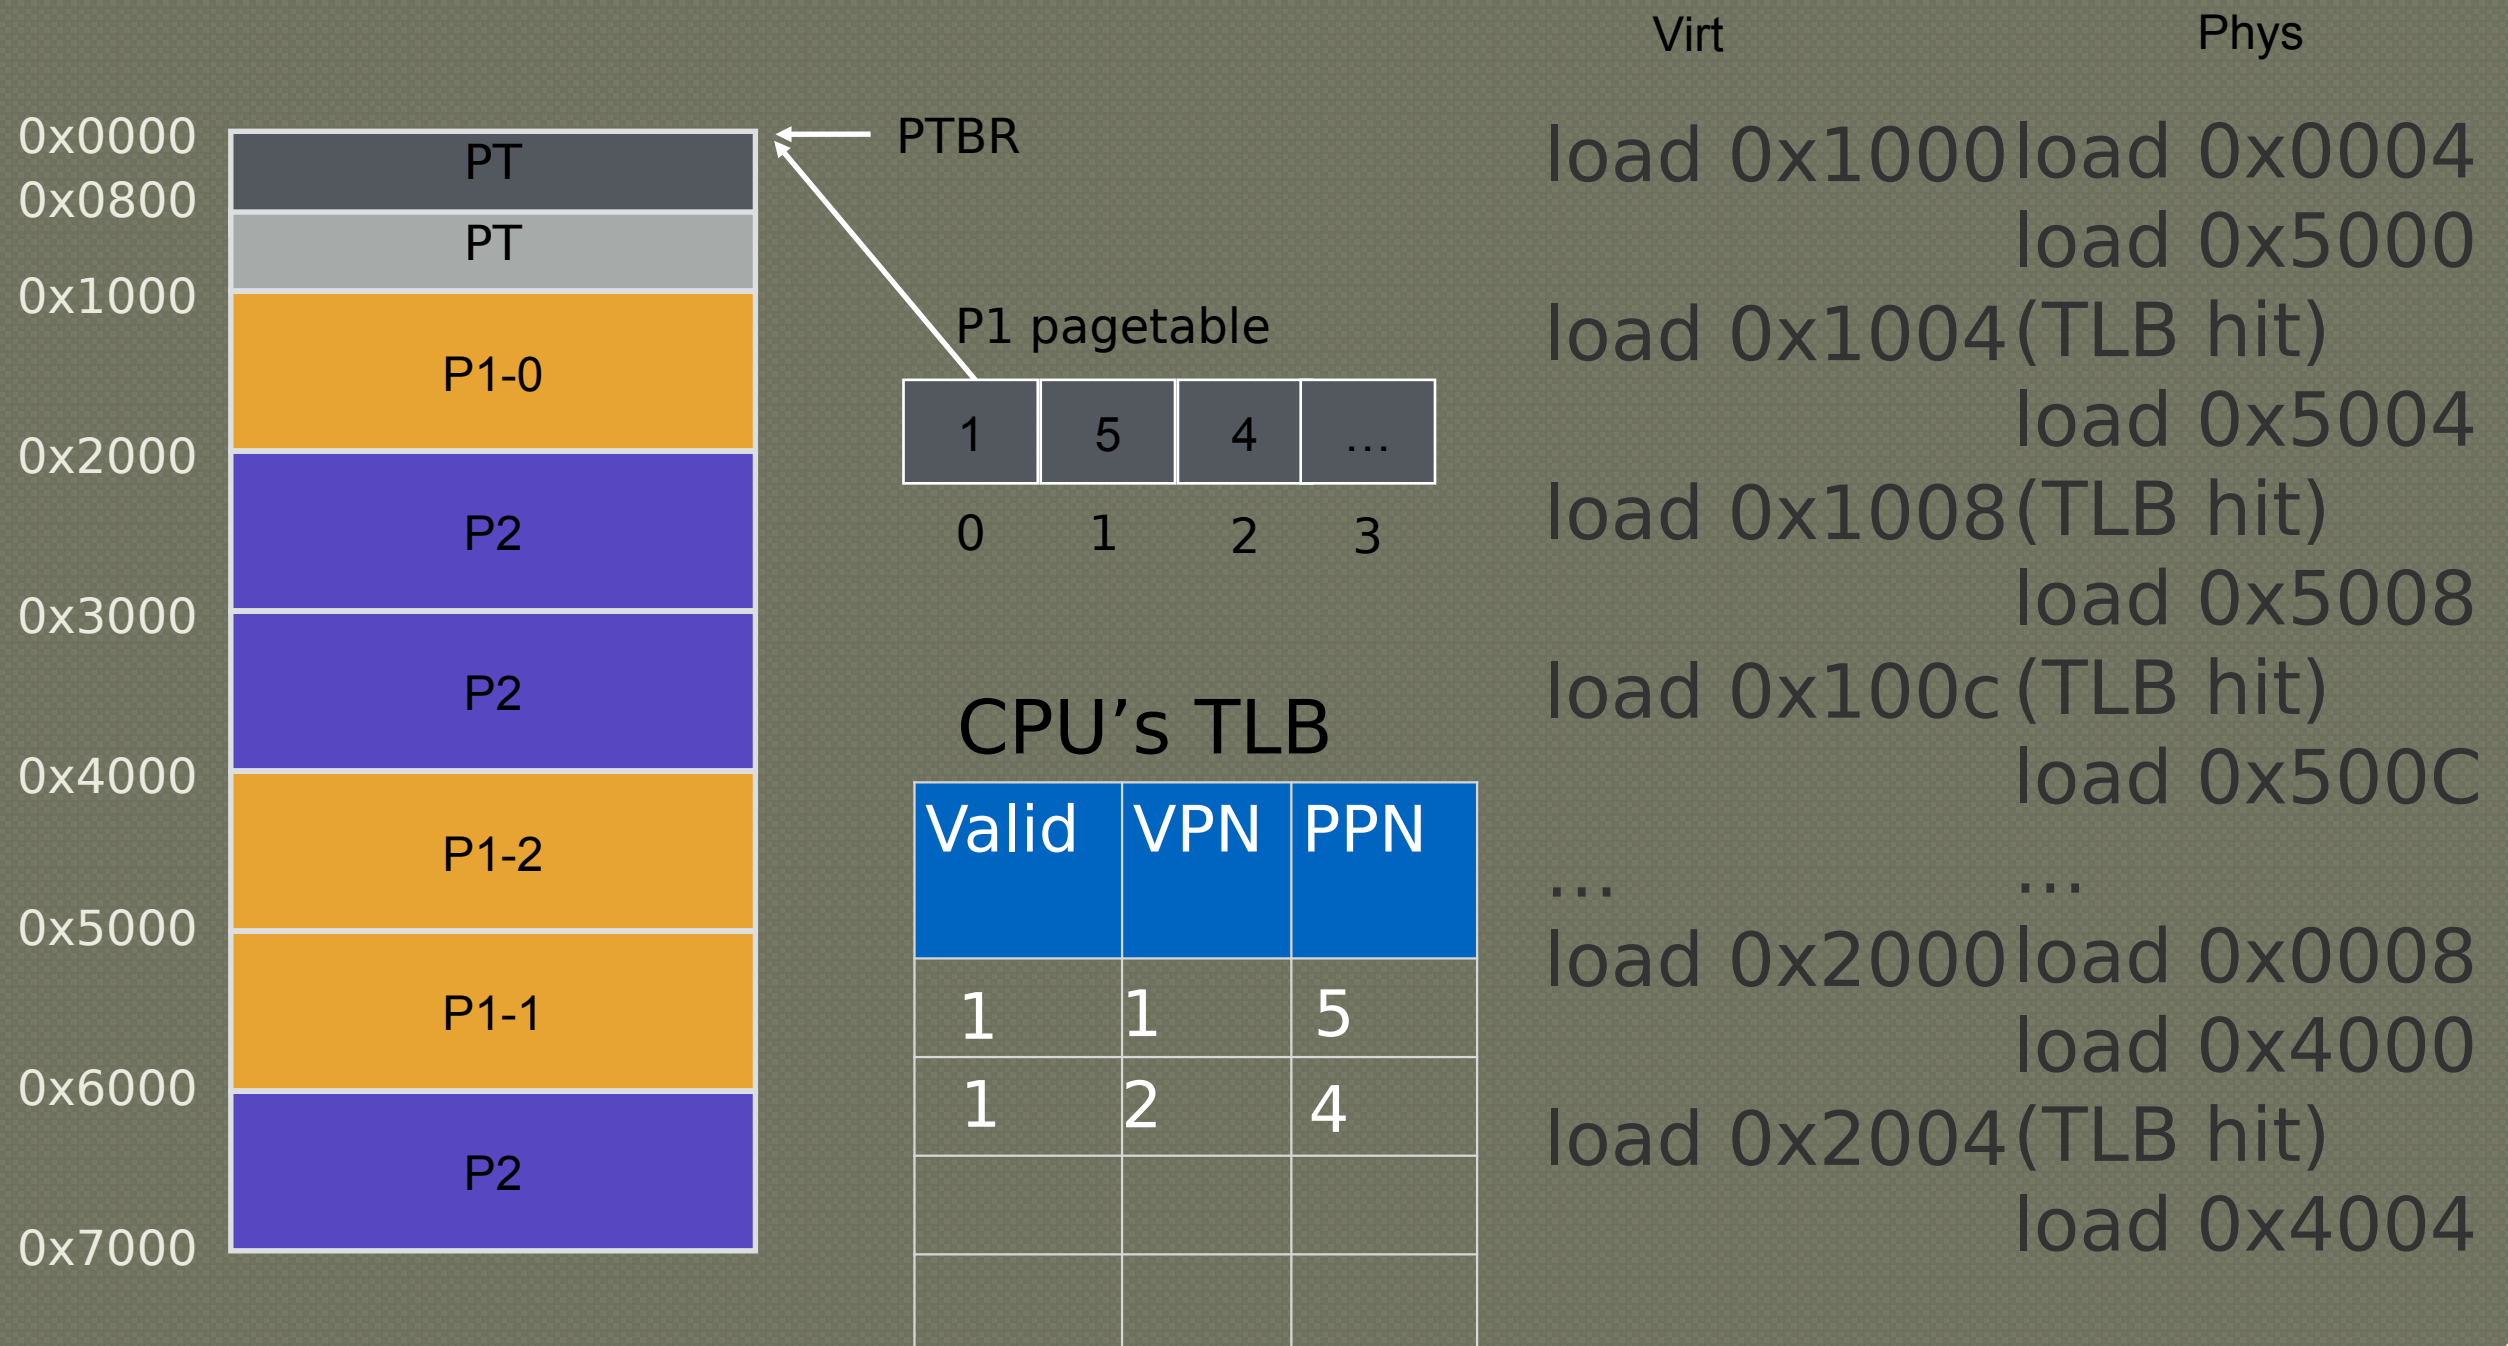

load 0x1008

load 0x100C

...

What will TLB behavior look like?

TLB Accesses: SEQUENTIAL Example

Size of each page table entry = 4 bytes

PERFORMANCE OF TLB?

```
int sum = 0;
for (i=0; i<2048; i++) {
    sum += a[i];
}
```

An integer is 4 bytes.
a[] is an array, its
allocated contiguously in
memory. It takes up
 $2048 * 4 = 8192$ bytes.
Which takes a min of two
and a max of 3 4K pages
(assume 2)

Calculate miss rate of TLB for data:

TLB misses / # TLB lookups

TLB lookups?

= number of accesses to a = 2048

TLB misses?

= number of unique pages accessed

= $2048 / (\text{elements of 'a' per 4K page})$

= $2K / (4K / \text{sizeof(int)}) = 2K / 1K$

= 2

Miss rate?

$2/2048 = 0.1\%$

Hit rate? (1 - miss rate)

99.9%

Would hit rate get better or worse with smaller pages?

Worse still have 2048 lookups but
would have to access more pages

TLB PERFORMANCE

How can system improve TLB performance (hit rate) given fixed number of TLB entries?

Increase page size

Fewer unique page translations needed to access same amount of memory

TLB Reach: The amount of memory accessible from the TLB.
$$\text{TLB Reach} = (\text{TLB Size}) \times (\text{Page Size})$$

TLB PERFORMANCE with Workloads

Sequential array accesses almost always hit in TLB

- Very fast!

What access pattern will be slow?

- Highly random, with no repeat accesses

Workload ACCESS PATTERNS

Workload A

```
int sum = 0;
for (i=0; i<2048; i++) {
    sum += a[i];
}
```

Workload B

```
int sum = 0;
srand(1234);
for (i=0; i<1000; i++) {
    sum += a[rand() % N];
}
srand(1234);
for (i=0; i<1000; i++) {
    sum += a[rand() % N];
}
```

Workload ACCESS PATTERNS

Spatial Locality

Sequential Accesses

Temporal Locality

Repeated Random Accesses

Workload Locality

Spatial Locality: future access will be to nearby addresses

Temporal Locality: future access will be repeats to the same data

What TLB characteristics are best for each type?

Spatial:

- Access same page repeatedly; need same vpn->ppn translation
- Same TLB entry re-used

Temporal:

- Access same address near in future
- Same TLB entry re-used in near future
-

Replacement policies

LRU: evict Least-Recently Used TLB slot when needed

(More on LRU later in policies next week)

Random: Evict randomly choosen entry

Which is better?

LRU Troubles

Valid	Virt	Phys
0	?	?
0	?	?
0	?	?
0	?	?

Workload repeatedly accesses same offset across 5 pages (strided access),
but only 4 TLB entries

What will TLB contents be over time?
How will TLB perform?

LRU Troubles

Valid	Virt	Phys
0	?	?
0	?	?
0	?	?
0	?	?

For this workload. What is the hit rate?

0x0000
0x1000
0x2000
0x3000
0x4000

loops

Hit rate = $\frac{\text{\#TLB hits}}{\text{\#TLB Lookups}}$
 $\text{\#TLB Lookups} = 5$
 $\text{\#TLB Hits} = 0$
 $\text{Hitrate} = 0/5$

Would be better to use Random replacement policy

TLB Replacement policies

LRU: evict Least-Recently Used TLB slot when needed

(More on LRU later in policies next week)

Random: Evict randomly choosen entry

Sometimes random is better than a “smart” policy!

Context Switches

What happens if a process uses cached TLB entries from another process?

Solutions?

1. Flush TLB on each switch
 - Costly; lose all recently cached translations
2. Track which entries are for which process
 - Address Space Identifier
 - Tag each TLB entry with an 8-bit ASID
 - how many unique ASIDs?
 - why not use PIDs?

Context Switches

What happens if a process uses cached TLB entries from another process?

Solutions?

1. Flush TLB on each switch
 - ❏ Costly; lose all recently cached translations
2. Track which entries are for which process
 - ❏ Address Space Identifier
 - ❏ Tag each TLB entry with an 8-bit ASID
 - how many unique ASIDs? $2^8 = 256$
 - why not use PIDs? PID is 32 bits, TLB is small, cannot hold 2^{32} processes page table entries.

TLB Example with ASID

Virtual	Physical
load 0x1444ASID: 12	load 0x2444
load 0x1444ASID: 11	load 0x5444

TLB:

Valid	Virt	Phys	ASID
0	1	9	11
1	1	5	11
1	1	2	12
1	0	1	11

TLB Performance

Context switches are expensive
Even with ASID, other processes “pollute”
TLB

- ❏ Discard process A’s TLB entries for process B’s entries

Architectures can have multiple TLBs

- ❏ 1 TLB for data, 1 TLB for instructions

HW and OS Roles

Who Handles TLB MISS? **H/W** or **OS**?

H/W: CPU must know where pagetables are

- CR3 register on x86
- Pagetable structure fixed and agreed upon between HW and OS
- HW “walks” the pagetable and fills TLB

OS: CPU traps into OS upon TLB miss

- “Software-managed TLB”
- OS interprets pagetables as it chooses
- Modifying TLB entries is privileged
 - otherwise what could process do?

Need same protection bits in TLB as pagetable

- rwx

Summary

- Pages are great, but accessing page tables for every memory access is slow
- Cache recent page translations => TLB
 - Hardware performs TLB lookup on every memory access
- TLB performance depends strongly on workload
 - Sequential workloads perform well
 - Workloads with temporal locality can perform well
 - Increase **TLB reach** by increasing page size
- In different systems, hardware or OS handles TLB misses
- TLBs increase cost of context switches
 - Flush TLB on every context switch
 - Add ASID to every TLB entry
